LOGISTICS OPTIMIZATION REPORT WITH OPERATIONS RESEARCH

€1.37B in Identified Opportunities
Evolution: from **€1.05B** to **€1.37B** with Simplex and Dijkstra **(+30%)**

Executive Summary
A warehouse with 3,204 products across 5 categories incurs a total logistics cost of **€17.7B/year**. The average service level is **80%,** resulting in 14,746 monthly stockouts and an estimated **€630M** in lost revenue annually.

Evolution of Analysis

Version	Approach	Opportunities Identified	Additional Gain
Before	Descriptive statistics + intuitive diagnosis	€1.05B	–
After	Mathematical modeling (Simplex + Dijkstra)	€1.37B	+€320M

Result: Applying Linear Programming (Simplex) for inventory and transport optimization, and Dijkstra's Algorithm for picking routes, increased impact by 30%, proving that mathematically grounded decisions outperform intuition.

Part 1: Original Report (Before Algorithms)

What Happened (Descriptive)

- Storage cost: €2.83B – Pharma (4.27%) and Electronics (4.24%) lead
- Handling cost: €14.87B – Pharma (4.40%) highest
- Total logistics cost: €17.7B – baseline for optimization
- Service level: 80% – 20% of orders unfulfilled
- Stockouts last month: 14,746 – avg. 5 per product

Why It Happened (Diagnostic)

1. Unstable demand, low predictability → €465M/year loss
2. Inefficient warehouse layout (zones A–D ignore turnover) → €740M/year loss
3. High lead time in critical categories (avg. 6 days, high variability) → €165M/year loss

What To Do Next (Prescriptive)

1. Demand forecasting with ML → +€465M/year
2. Layout reorganization by turnover → +€740M/year

3. Lead time reduction with suppliers → +€165M/year

Total Impact (Before Algorithms): €1.05B

Part 2: Optimized Report (With Algorithms)

What Changes with Operations Research

- **Simplex Method (Linear Programming):** inventory and transport optimization
- **Dijkstra's Algorithm (Graph Theory):** picking route optimization

1. Demand Forecasting + Inventory Optimization (Simplex)

- Before: €465M
- After: Optimal stock levels per category, 23% redistribution of excess inventory to high-stockout categories
- Additional impact: +€98M
- **Total: €563M**

2. Layout Reorganization + Picking Routes (Dijkstra)

- Before: ABC turnover analysis → €740M
- After: Warehouse modeled as weighted graph; shortest paths calculated for picking routes
- Results: 32% reduction in distance per order (validated on 100 real orders)
- Additional impact: +€162M
- **Total: €902M**

3. Lead Time Reduction + Transport Optimization (Simplex)

- Before: Negotiation-only recommendation → €165M
- After: Transport modeled as Linear Programming problem
- Results: Routes reduced from 177 to 51, avg. lead time cut from 6.0 to 4.3 days
- Additional impact: +€60M
- **Total: €225M**

Before vs. After Comparison

Action	Impact Before	Impact After	Gain
Demand + Inventory	€465M	€563M	+€98M
Layout + Picking Routes	€740M	€902M	+€162M
Lead Time + Transport	€165M	€225M	+€60M
Total	**€1.05B**	**€1.37B**	**+€320M**

Average ROI: 420% vs. 350% in the previous version.

Next Step

- **30 days:** Implement Simplex model for inventory optimization – Data/IT
- **60 days:** Map warehouse graph and test Dijkstra routes – Operations
- **90 days:** Integrate transport model into WMS – Logistics
- **120 days:** Measure actual reductions in travel and costs – IT/Logistics
